# Clockor2: Inferring global and local strict molecular clocks using

## root-to-tip regression

Leo A. Featherstone\*,1, Sebastian Duchene†,1, Wytamma Wirth†,1

## Abstract

- <sup>2</sup> Molecular sequenced data from rapidly evolving organisms are often sampled at different points in time.
- Sampling times can then be used for molecular clock calibration. The root-to-tip (RTT) regression
- 4 is an essential tool to assess the degree to which the data are amenable to such analyses and behave
- 5 in a clock-like fashion. Here, we introduce clockor2, a client-side web application for conducting RTT
- 6 regression. Clockor2 uniquely allows users to quickly fit local and global molecular clocks, thus handling
- 7 the increasing complexity of genomic datasets that sample beyond the assumption homogeneous host
- populations. Clockor2 is efficient, handling trees of up to 10<sup>5</sup> tips, with significant speed increases
- 9 compared to other RTT regression applications. Although clockor2 is written as a web application, all
- data processing happens on the client-side, meaning that data never leaves the user's computer. Clockor2
- is freely available at https://clockor2.github.io/.
- Keywords: Molecular clock, evolutionary rate heterogeneity, root-to-tip regression.

## 13 Introduction

Phylodynamic analyses make use of genetic sequence data to understand the evolution and epidemiological (or ecological) dynamics of a pathogen. Importantly, phyodynamics achieves its greatest value when generating insight about infectious disease dynamics outside the purview of epidemiology. This 16 frequently occurs at population interfaces, such as during transmission across host sub-populations, geo-17 graphical boundaries or host species. The essential component to all phylodynamic modelling is always the assumption of a molecular clock relating epidemiology and evolution. 19 The simplest molecular clock model is the strict clock, which assumes a constant rate of substitution 20 per unit time, known as the 'evolutionary rate'. When the evolutionary rate is constant throughout 21 a phylogenetic tree, the term global molecular clock is used. In contrast, a local strict clock refers to 22 the situation where different substitution rates apply to different monophyletic groups within a tree (Ho and Duchêne, 2014). The branches of local clocks are sometimes referred to as 'foreground' while the remaining branches are known as the 'background' (Yoder and Yang, 2000). The assumption of a local clock may for example reflect samples from different host populations, host species, or pathogen lineages (Worobey et al., 2014). For example, clockor2 includes a default example from Porter et al. (2023), where local clocks are fit to human and mink SARS-CoV-2 host populations. Clockor2 enables rapid inference 28 of global and local strict molecular clocks from phylogenetic trees where tips are annotated with sampling times, using root-to-tip regression (RTT). Several other tools allow for the inference of strict molecular

et al., 2018; Sagulenko et al., 2018; Volz and Frost, 2017).

Phylodynamic datasets are and will continue to grow in size and scope Featherstone et al. (2022). For
example, datasets of thousands to tens-of-thousands have been used to understand the spread of SARSCoV-2 at national and international scales, as well as study the emergence of variants of concern (VOC),
and transmission to other species (du Plessis et al., 2021; Hill et al., 2022; Nadeau et al., 2023; Porter

clocks via RTT, but none readily offer the ability to fit local clocks models (Rambaut et al., 2016; Hadfield

et al., 2023). Larger datasets, as a function of their size, are more likely to be sampled from increasingly distinct populations, meaning that local clocks will become increasingly important. Currently, testing the fit of a local clock over alternative models, such as global or relaxed clocks, frequently requires intensive computational efforts using common Bayesian phylodynamic applications such as BEAST or RevBayes 40 (Bouckaert et al., 2019; Suchard et al., 2018; Höhna et al., 2016), each requiring hours to days of computational time. Clockor2 uniquely offers a scalable and accessible client-side web application to perform the same function, with results available in seconds to minutes to inform subsequent phylodynamic analysis. 43 Specifically, clockor2 allows users to perform RTT regression for fitting global and local clocks. The 44 user begins by dropping or importing a newick tree. Sampling dates and group identifiers can be parsed from tip labels or separate files on input. Like other RTT regression applications, clockor2 also allows users to infer the best fitting root based on the  $R^2$  value of the RTT regression, a key indicator of clocklike evolution. It also offers users a local clock-search function to test assumptions about local clocks in a dataset.

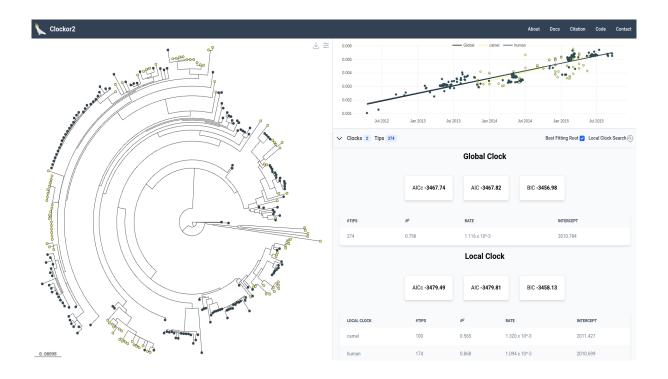

Figure 1: lockor2 presents the tree along size RTT regression data. Users can toggle between local and global clocks and alter the appearance of the tree.

## 50 Methods

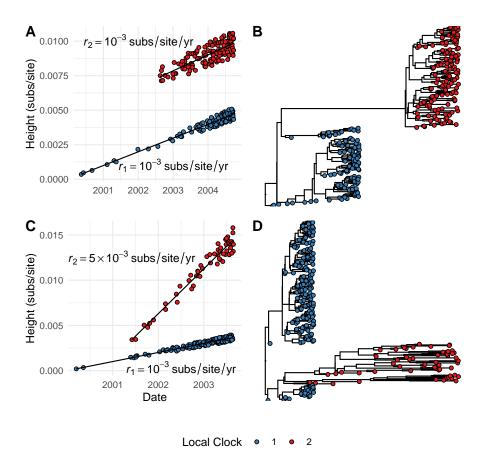

Figure 2: Simulated examples of how local clocks may manifest in trees and RTT regression data. (A) RTT regression data for two local clocks with similar rates separated by a long branch. (B) A tree characteristic of two similar local clock rates separated by a long branch. (C) RTT regression data where two local clocks have different evolutionary rates. (D) A tree characteristic of two local clocks with different rates.

### General model for global and local strict clocks

RTT regression consists in modelling the evolutionary rate as the slope of a linear regression between distance from the root to each tip (i.e. RTT), typically in units of substitutions per site (subs/site), and the sampling date of each tip. If we denote the evolutionary rate as r (usually in units of subs/site/time), RTT distance as d (usually in units of subs/site), o as the intercept (interpreted as origin), and sampling times as t, then the model for a global strict clock takes the form:

$$d = rt + o + \epsilon$$

where epsilon is an error term.

53

Clockor2 uses a generalisation of this model to accommodate local clocks. For a given tree with a set of tips T, we define local clocks as pertaining to groups of tips  $g_i$  and a rate parameter for each  $(r_i)$ . For a strict clock model with two local clocks, we then write:

$$d = \begin{cases} r_1 t + o + \epsilon, & \text{if tip } \epsilon \leq g_1 \\ r_2 t + o + \epsilon, & \text{if tip } \epsilon \leq g_2 \end{cases}$$

We refer to groups instead of clades because while collections of tips belonging to one local clock

necessarily share a common ancestor, they do not necessarily comprise a whole clade. This occurs when
two or more local clocks are nested. The tips comprising the outer clock(s) cannot comprise a whole clade
if another local clock is nested within it. For example, local clock 1 in Fig. 2 B,D does not comprise a
clade (i.e. is not monophyletic) because local clock 2 is nested within it.

This general model then captures two key scenarios where local clocks may be appropriate. The first
is where rates are similar between local clocks, but separated by a long branch (Fig. 2A-B). For example,
in the evolution of VOCs in SARS-CoV-2 or due to temporally-sparse sampling in the case of ancient

Yersisnia pestis samples Tay et al. (2022); Eaton et al. (2023). The second scenario is where rates differ
between local clocks (Fig 2 C-D). For example, this can occur when a pathogen spreads in different host
species, such as has been observed for SARS-CoV-2 in mink and human hosts (Porter et al., 2023).

For each group of tips defining a local clock, we independently conduct a RTT regression to estimate the evolutionary rate (slope).  $R^2$  values for each clock are then an indication of clock-like behaviour for each local clock. Clockor2 focuses on  $R^2$  as an indication of appropriateness of a strict clock instead of other regression summary statistics, such as root mean squared error, because it offers the most straightforward interpretation of clock-like evolution.  $R^2$  values of one indicate perfect clock like evolution, while values of 0 indicate a lack of a molecular clock.

Local clock and or global clock configurations can then be compared using an information criterion
that combines the likelihood of each local clock's RTT regression while penalising the number of inferred
parameters (three for each clock - slope, intercept, and variance). Clockor2 allows users to use either the
Bayesian Information Cirterion (BIC), Aikake Information Criterion (AIC), or corrected Aikake Information Cirterion (AICc). We recommend using the BIC because it most heavily penalises the addition
of extra parameters, and local clocks in turn.

Derivations of the above information criteria for the local clock model are given in the supplementary methods. Briefly, these exploit the assumption of independent sampling to factor the likelihood across local clocks. Note however that the assumption of independent sampling is flawed because samples necessarily share some ancestry by the assumption of a phylogenetic tree. In other words, ancestral branches are counted over many times in the calculating the distance from root to tip for each sample. However, this is a limitation of the RTT regression approach more broadly, rather than clockor2 itself.

#### 82 Algorithm for local clock search

Where it is hypothesised that a datasset contains local clocks, clockor2 provides functionality to corroborate the this hypothesis by performing a search for local clocks in the tree. Briefly, the algorithm takes a maximum number of clocks and a minimum number of tips (group size) for each local clock as input parameters. It then iterates through all combinations of internal nodes from which local clocks can descend to induce corresponding local clock configurations. Importantly, the clock search algorithm tests for a

- number of clocks up to and including the maximum number so that more parsimonious configurations
- 89 with fewer clocks may be found. Configurations are compared using the information criteria outlined
- 90 above. Again, we recommend the BIC as it penalises additional parameters (ie. additional local clocks)
- most heavily. See here for an animation of the clock search algorithm.
- We stress that this algorithm is intended to corroborate hypotheses about a particular local clock
- configuration, but is not intended to be performed as a blind search for local clocks. This is because it
- 94 is highly prone to over-fitting where the maximum number of clocks is inflated, as outlined later in the
- 95 results section.
- The clock-search algorithm operates in polynomial time (see supplementary material). Efficiency is
- 97 improved by reducing the maximum number of local clocks in the search, increasing the minimum group
- 98 size, and contingent on the topology of the underlying tree. However, the former two parameters exert a
- 99 far greater effect on efficiency than topology.

#### 100 Clock-search algorithm simulation study

We conducted a simulation study to test the accuracy of the clock-search algorithm. We started with a core set of 100 simulated trees of 250 tips and added a local clock descending from a randomly selected node such that it would contain between 50 and 150 tips. For each, we simulated a 5-fold rate increase occurring in either the stem branch leading to the group/clade, or throughout the group. These scenarios are characterised in Fig 2 C,D respectively. For each of the resulting 200 trees, we applied the clock search algorithm with a minimum group size of 50 tips and a maximum number of of 2-5 clocks. The case of a maximum of 2 clocks tests for baseline accuracy where search parameters match reality. Searches with a maximum of 3-5 clocks test for over-sensitivity in the algorithm where the maximum number of clocks is inflated. All clock-search tests use the BIC.

### Finding the Best Fitting Root

Clockor2 selects the best fitting root based on the  $R^2$  of a global clock model for the input tree. It follows 111 the same algorithm as implemented in Tempest Rambaut et al. (2016), but makes use of parallelisation 112 to improve speed for larger trees. Briefly, the tree is rooted along the branch leading to each internal node or tip, an RTT regression is performed, and the root leading to the highest  $R^2$  value is selected. 114 When rooting along a branch of length greater than  $10^{-8}$ , clockor2 starts at the midpoint and then 115 optimises the root position using the golden-search-section algorithm. Shorter branches are assumed to 116 be effectively zero length, and hence there is no need to optimise the position of the root locally. 117 The best fitting root is inferred using a single, global clock because this presents the most parsimonious 118 model of the evolutionary rate for a given tree. The fit of more elaborate local clock models can then 119 be compared to this using information criteria and/or comparing the  $R^2$  values of each model. Clockor2 120

#### 123 Dependencies

121

122

Clockor2 has three key dependencies for handling, and plotting trees and RTT data. Trees are handled and manipulated using the phylojs library Cite preprint for phylojs?. Phylocanvas is used to viaualise trees and plotly.js is used to plot RTT data (Abudahab et al., 2021).

does not find the best fitting root for local clock models because the search space of best fitting roots

and local clock configuration quickly becomes prohibitive and is possibly unidentifiable.

## $_{127}$ Results

#### 128 Efficiency

Clockor2 can process trees of up to 10<sup>5</sup> tips. Finding the best fitting root makes use of parallelisation to increase speed. Speedup is therefore proportional to the number of threads or cores available, in addition to the chose of browser and computer. For example, Clockor2 is faster than TempEst v 1.5.3 a 2021 Mackbook pro with 16Gb of memory and 8 cores running chrome v113.0.5627.126, (Table 1). However,
we found Clockor2 to be comporable or slower on other combinations of processor and browser.

Tips	Clockor2	TempEst
100	0.26	< 1
500	1.53	2.40
1000	5.35	10.28
5000	189.02	272.29
10000	1082.63	1310.34

Table 1: Time taken to find the best fitting root for test trees of 100, 500, 1000, and 5000 tips using clockor2 and TempEst v1.5.3 on a 2021 Macbook woth 16Gb of memory and 8 cores running chrome v113.0.5627.126. Times vary with computer and browser. In general the relative efficienty of Clockor2 will increase with the number of cores.

#### clock-search accuracy

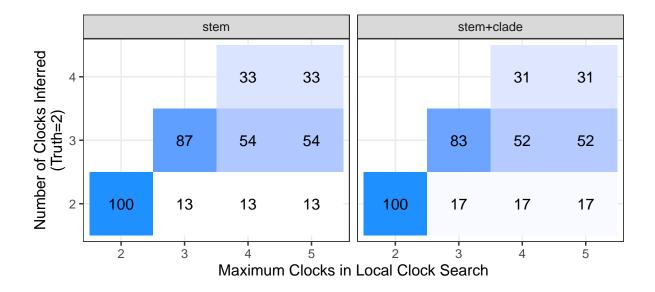

Figure 3: Confusion matrices comparing the number of inferred clocks against the maximum number of clocks allowed by each search, with a true number of 2 clocks in each search. "stem" and "stem+clade" refer to either a rate increase along only the stem of a clade, or with the rate increase continuing in the clade. The true value is 2 and accuracy decreases as the maximum number of clocks allowed by the clock-search algorithm increases. The colour of and number in each tile reflect the number of analyses out of 100 selecting the corresponding number of clocks.

For clock searches with a maximum number of 2 clocks, the clock-search algorithm correctly identified 2 local clocks in the simulated data with complete accuracy (Fig. 3). However, when the algorithm was allowed to search for configurations with 3-5 clocks, only 13 and 17 analyses correctly recovered 2 clocks for the stem only and stem+clade rate increases respectively. Although we used the BIC, the most conservative information metric used in clockor2, the clock-search algorithm is clearly still highly prone to over-fitting local clock configurations to data where a higher number of clocks allows for tighter clusters of points in the RTT data to be found.

To this end, we again emphasise that the clock-search algorithm is only intended to be used as a tool testing a number of clocks up to and including the hypothesised number, but never more. It should never be used to blindly search for local clocks in the absence of a biological hypothesis. For example, to demonstrate intended use we used the clock search with a minimum group size of X and max number of clocks of 2 to test for the presence of two local clocks in SARS-CoV-2 data taken from human and mink hosts in Porter et al. (2023). We found that the clock search supported the presence of two clocks dividing mink samples from the Netherlands and the rest of the data, supporting the inference of a second clock for mink hosts. Conversely, improper use would be searching for a number of clocks above the biologically-informed hypothesis of 2 local clocks.

## 51 Discussion

Clockor2 provides a flexible and scalable front-end web based RTT regression platform. Its extension to fitting local clocks allows it to accommodate the growing complexity of phylodyanmic datasets as genomic epidemiology plays a growing role in infectious disease surveillance.

As a front end application, clockor2 is also highly accessible with no installation steps required, although users have option of saving the site to run locally. Wherever there is a browser, it is possible to conduct an RTT regression using clockor2 with the data never leaving the user's computer.

#### Future Directions

In the future it will be possible to re-implement core functionality in increasingly popular and highly efficient programming languages, that can compile to Web-Assembly format. For example, as the bioinformatics ecosystem in Rust continues to develop, it will be possible to further improve the efficiency of clockor2 using packages such as Bio-Rust (Köster, 2015).

## Data availability

- All code required to replicate the simulation study and figures in the paper is available at https:
- //github.com/LeoFeatherstone/clockor2Paper. The code for clockor2 is open source at https:
- 166 //github.com/clockor2/clockor2.
